

AI Engineer — Take-Home

The task

Attached are ~30 transcripts for **Rockwall** (earnings calls, analyst meetings, general meetings) covering the last several years.

Build a agent-based system that:

1. Extracts forward-looking claims made by management
2. Tracks each claim across subsequent transcripts and any other sources you choose to bring in
3. Determines whether each claim materialized, partially materialized, didn't, or remains unresolvable

Important: walk-forward

Process transcripts in chronological order, as if each were arriving live. We want to see how your system behaves as new data arrives — claims being resolved, revised, or quietly dropped over time. An important part of this exercise is how state is handled across sessions and time.

What we care about

We should be able to see, for any claim: when it was made, by whom, and the progress and final resolution — traceable to evidence.

Come ready to discuss:

- Your taxonomy of claim types and how you handle hedged or unfalsifiable language
- How you evaluated your system
- Where it fails — both specific bugs and broader limits of the approach
- What you'd build next to make it materially better
- How would your approach scale to 30k, 300k, 3million documents? Is there a limit of your approach?

Format

Use any framework or models you like. There is no single correct way of going about this. Feel free to use websearch tools, etc if your approach requires. We do not expect you to bring in external data sources unless you think its critical.

We'll do a 1-hour screen-share where you walk us through the system live. No pre-interview deliverables required — share whatever's useful on the call (repo, outputs, notes, vizualisations). Questions welcome.
